20 **1. Introduction**

21 The global focus on sustainability in agronomic industries has changed the
22 way in which these enterprises do business. When strategies for a sustainable
23 winegrowing industry are assessed, there is a trade-off between balancing the
24 amount of resources invested and the resultant yield verses quality produced.
25 This dilemma exists across agriculture through shared fundamental consid-
26 erations such as water use and nitrogen levels (???). Quality in viticulture
27 (the cultivation of grapes for wine production) is driven through its integra-
28 tion within the wine industry; with a wine's potential quality being initially
29 defined through the chemical makeup of the grapes used in its production.
30 The consideration of sustainability within viticulture is further complicated
31 by environmental and socio-demographic pressures. In the Australian con-

32 text, these include: biosecurity, climate and international market demands.
33 In this analysis we observe relationships between yield and quality through
34 the use of linear models. An extensive amount of research into a variety of
35 factors' effect on grape quality and yield exists; but due to the lack of long-
36 term and in-depth data, individual effects are often studied in isolation (?).
37 The lack of consolidated datasets also restricts the ability to gain statistical
38 insights at large scales and across multiple regions (??). The dataset used for
39 this analysis includes data collected for the past 10 years from a multitude
40 of vineyards located over a diverse range of Australian winegrowing regions.
41 We aim to use this broad dataset to describe the relationship of input re-
42 sources to the output yield and quality of vineyards. The practical addition
43 of this aim is a baseline for comparison - given a vineyard within Australia,
44 one could extrapolate their comparative efficiency with regard to the trade-
45 off between invested resources, yield and quality. In achieving this we will
46 also confirm the existence of a yield verse quality trade off within Australian
47 winegrowing; one not prior confirmed explicitly across such varying regions,
48 scales and climates.

49 **2. Methods**

50 We created four linear models to explore relationships between resource-
51 use and vineyard outputs (see Table??). The data was sourced from Sustain-
52 able Winegrowing Australia and Wine Australia. Variables used included:
53 yield, average sale price, region, water use, emissions, area harvested and
54 year. After fitting to the data, each model was validated using k-fold cross
55 validation.

Table 1: Summary of models; their predictors, covariates and variable interactions.

	Response	Predictors	Covariates	Interactions
Model 1	Yield	Water Used Scope 1 Emissions	Area Harvested Year GI Region	N/A
Model 2	$\frac{\text{Yield}}{\text{Area Harvested}}$	Water Used Scope 1 Emissions	Area Harvested Year GI Region	Area Harvested * Scope 1 Emissions Area Harvested * Water Use Year * Region
Model 3	Yield \times Average Sale Price	Water Used Scope 1 Emissions	Area Harvested Year GI Region	N/A
Model 4	$\frac{\text{Yield} \times \text{Average Sale Price}}{\text{Area Harvested}}$	Water Used Scope 1 Emissions	Area Harvested Year GI Region	Area Harvested * Scope 1 Emissions Area Harvested * Water Use Year * Region

2.1. Analysis

Before models were fit to the data, Pearson Correlation Coefficients were used to look at the existence of linear relationships between predictor variables. These relationships were summarised in correlation matrices to compare the level of interaction present between predictor variables. The relationships between the predictors and response variables were then modelled using General Linear Models. Both the Pearson Correlation Coefficients and General Linear Models were created using the R statistical programming language (?). General Linear Models were chosen as they offer the ability to produce statistical models that are explicit in the relationships between predictors and response variables. General Linear Models also allow the exploration of interactions between predictors and present easily comparable

68 differences in the influence and magnitude of relationships. A variety of alter-
69 nate methods were also explored, including: Splines, hierarchical regression,
70 General Additive Models, and Generalised Linear Models. These alternative
71 approaches were not used as final models due to offering no further insights
72 or improvements in accuracy.

73 The response variables of the models were yield and quality. Yield was de-
74 fined as the total tonnes of grapes harvested. For the purpose of this study,
75 quality was defined by the financial value of winegrape crops' average sale
76 price per tonne. The definition of quality was an important consideration,
77 as quality can be defined in a variety of ways, for example analysing grapes':
78 aroma, chemical composition and color. Using sale price as a defining trait
79 of quality was due to the market value of winegrapes being reliant on grape
80 quality and because Wine Australia explicitly defines grape quality through
81 the use of discrete price brackets in their annual reports ; the generalisation
82 made to reflect quality through using average price assumed a due diligence
83 of those who purchased the grapes (?). Both response variables were exam-
84 ined as totals and as scales of area harvested. Values were compared in this
85 manner to observe how economies of scale affect the use of resources.

86 *2.2. Significant Tests*

87 *2.3. Data*

88 Data used in this analysis was sampled by Sustainable Winegrowing Aus-
89 tralia and Wine Australia. Sustainable Winegrowing Australia is Australia's
90 national wine industry sustainability program, which aims to facilitate grape-
91 growers and winemakers in demonstrating and improving their sustainability

(?). Wine Australia is an Australian Government statutory authority governed by the Wine Australia Act 2013 (?).

Data sampled by Wine Australia was collected via phone surveys and included: summary statistics such as yield and average price of sale per tonne; these values were summarised by region and grape varietal. Data recorded by Sustainable Winegrowing Australia was entered manually by winegrowers using a web based interface with some fields being optional, variables included: region, harvest year, yield, area harvested, water used and fuel used (diesel, petrol, biodiesel and LPG). To enable direct comparisons between fuels, they were converted to tonnes of Carbon Dioxide equivalent.

The inclusion of Wine Australia data was due to average sale price being an optional field in Sustainable Winegrowing Australia's dataset. Regional average prices from Wine Australia were filled into values that were missing from the Sustainable Winegrowing Australia data; the common practice of purchasing grapes at regional prices was an important consideration in this decision. Two subsets of data were then created for the analysis. The first subset contained all vineyards and was used for Models 1 and 3. The second subset contained vineyards which either recorded a value for average price of sale per tonne through Sustainable Winegrowing Australia, or were within a region with an average price of sale recorded by Wine Australia; this subset was used for Models 2 and 4. These subsets meant that the data would be limited to samples which had recorded values for the response variables (see Table??), where every sample had a recorded value for yield but not average price of sale per tonne.

The first subset of data was used for Model 1 and Model 2 (see Table??).

117 This subset contained 5298 samples spanning the period from 2012 to 2022,
118 covering 55 GI Regions and 1261 separate vineyards.

119 The second subset of data, was limited to vineyards that recorded a value
120 for their average sale price of grapes per tonne. This subset was used for
121 Model 3 and Model 4 (see Table??); and contained 2878 samples spanning
122 the period from 2015 to 2022, covering 51 GI Regions and 944 separate vine-
123 yards. 1842 of the values for average price of sale per tonne were extracted
124 from Wine Australia surveys with the remaining 1036 being from Sustainable
125 Winegrowing Australia’s dataset.

126 Additional variables were considered for analysis but were excluded due to
127 being either underreported or had insignificant contributions to model accu-
128 racies. Variables explored but not used due to low reporting values included:
129 fertiliser, and scope 2 emissions. Variables considered but ultimately removed
130 due to a lack of significant contributions to models, included: the use of re-
131 newable energy, contractor use, and pressures such as frost, fire and disease.

132 Data preprocessing was conducted prior to analysis using the Python pro-
133 gramming language (?). Preprocessing included logarithmic transformations,
134 centring and scaling by standard deviation. Variables such as scope 1 emis-
135 sions, which required prior calculations were also computed using Python.

136 2.4. Total Emissions

137 The equation given from the Australian National Greenhouse Accounts
138 Factors, shown as

$$139 \quad tCO_2e = \frac{Q \times EC \times EF1 + EF3}{1000}, \quad (1)$$

140

141 was used to convert the quantity of fuel in litres, Q , using a prescribed Energy
142 Content, EC , and emission factors of scope one, $EF1$, and scope three, $EF3$,
143 to tonnes of Carbon Dioxide Emission equivalent, $tCO2e$ (?). Emissions were
144 calculated for total diesel, petrol, bio-diesel and LPG used.

145 2.5. Region

146 Differences in vineyard locations were captured through the use of Ge-
147 ographical Indicator Regions (GI Regions). Each GI Region has its own
148 unique mixture of climatic and geophysical properties that describes a unique
149 winegrowing region within Australia; these regions were predefined by Wine
150 Australia (???). Both Wine Australia and Sustainable Winegrowing Aus-
151 tralia used the same GI Region format to describe location.

152 The site of a vineyard predetermines several physical parameters such as cli-
153 mate, geology and soil; making location a widely considered key determinant
154 of grape yield and quality (???). The climatic properties of each GI Re-
155 gion were summarised by using predefined classifications as per the ? user
156 manual. The user manual describes climates by rainfall and temperature,
157 creating supersets of Regions of similar climatic properties. The climatic
158 groups were used to illustrate similarities and differences occurring in areas
159 larger than GI Regions.

160 2.6. Model Validation

161 Models were validated using K-fold cross validation calculated through
162 the R Caret Package (?). K-fold cross validation works by removing a subset
163 of data from the sample used to train models and then predicts those variables

164 to determine how sensitive the model is to changes in the sample data. For
165 this analysis each model was validated using 10 folds, repeated 100 times.

166 **3. Results**

167 *3.1. Data*

168 Each variable was logarithmically transformed and then centred around
169 a mean of 0. The values of these variables were then divided by standard
170 deviation creating a comparable ratio intrinsic to each variable. Table ??
171 shows the summary statistics of each variable, to contextualise these ratios
172 to real values.

173 *3.2. Exploratory Analysis*

174 Linear relationships between variables were explored using Pearson Cor-
175 relation Coefficients. Values for these coefficients reflect the linear relation
176 between two variables, on a scale between -1 and 1; the magnitude and sign
177 of a coefficient indicates the strength of the relation, and whether the rela-
178 tion is positive or negative respectively. This was undertaken for data on the
179 original scale and for data as a logarithmic transform. The logarithmic trans-
180 formed data showed the strongest correlations, likely due to a skew caused
181 by a greater number of smaller vineyards within the dataset (see Table ??).
182 Transforming data prior to calculating the coefficients changes several things:
183 The logarithmic transform of the data alters the interpretation of the coef-
184 ficients to percentage change - a coefficient will be indicative of the change
185 in percentage of one variable compared to the other; scaling by standard de-
186 viation also changes this interpretation to be a percentage of that variables

Table 2: Summary statistics of each continuous variable.

Variable	Mean	Standard Deviation	Minimum	Maximum
Yield	7.757E+02	2.179E+03	1.000E+00	7.231E+04
Area Harvested	6.670E+05	1.337E+06	7.000E+02	2.436E+07
Water Used	7.471E+06	5.646E+08	1.000E+00	4.268E+10
Scope One Emissions	4.173E+04	8.571E+04	6.755E+00	2.110E+06
$\frac{\text{Yield}}{\text{Area}}$	1.009E+01	8.127E+00	4.000E-02	8.634E+01
Average Sale Price	1.477E+03	9.216E+02	1.600E+02	2.600E+04
$\frac{\text{Average Sale Price}}{\text{Area Harvested}}$	1.347E+02	5.711E+02	1.753E-01	2.979E+04

Table 3: Variable Pearson correlation values for logarithmically transformed values.

Variable	Yield	Area Harvested	Water Used	Scope One Emissions	$\frac{\text{Yield}}{\text{Area}}$	Average Sale Price	$\frac{\text{Average Sale Price}}{\text{Area Harvested}}$
Yield	1.00E+00	7.44E-01	-4.31E-03	7.29E-01	3.50E-01	-2.26E-01	-1.64E-01
Area Harvested	7.44E-01	1.00E+00	-5.33E-03	8.92E-01	7.85E-02	-1.18E-01	-2.04E-01
Water Used	-4.31E-03	-5.33E-03	1.00E+00	-1.93E-03	-5.60E-03	-3.56E-02	-2.67E-02
Scope One Emissions	7.29E-01	8.92E-01	-1.93E-03	1.00E+00	9.36E-02	-9.42E-02	-1.93E-01
$\frac{\text{Yield}}{\text{Area}}$	3.50E-01	7.85E-02	-5.60E-03	9.36E-02	1.00E+00	-4.85E-01	-1.70E-01
Average Sale Price	-2.26E-01	-1.18E-01	-3.56E-02	-9.42E-02	-4.85E-01	1.00E+00	4.73E-01
$\frac{\text{Average Sale Price}}{\text{Area Harvested}}$	-1.64E-01	-2.04E-01	-2.67E-02	-1.93E-01	-1.70E-01	4.73E-01	1.00E+00

187 standard deviation. Scaling by standard deviation also makes the Pearson
 188 Correlation Coefficient equal to the covariance of the two variables. With all
 189 this in mind, when considering the logarithmically transformed variables, a
 190 coefficient of 1 would indicate that: given the change of one variable by one
 191 percentage of its standard deviation, the other variable would change by one
 192 percent of its own standard deviation. The importance of this is the dimen-
 193 sionless nature of these relationships and that it can be translated directly
 194 to any vineyard's case that has a well known distribution.
 195 To determine if a coefficient was indicative of a strong relationship, confidence
 196 intervals were used. P-values reflected the significance of a given correlation
 197 coefficient when considering its relation to sample size via its incorporation as
 198 an element of standard error. Strong relationships were found to be present
 199 as all P-values, except for the non-transformed values for water used, were
 200 considered significant ($P < 2.200E-16$).

201 3.3. General Linear Models

202 General Linear Models were used to describe how response variables re-
 203 lated to predictors' values. Log transformed variables were used as inputs to
 204 these models as they resulted in higher R^2 values and described the relation-
 205 ships proportionally; reflecting coefficient values as percentages of a variable's
 206 standard deviation. Each model showed a strong relationship between the
 207 predictors and the response (see Table ??). Model accuracy was measured
 208 in R^2 , as this allowed an easy comparison between their performances and
 209 their validation.

Table 4: Summary of models; their performance, F-statistics and Residual error.

	R ²	Adjusted R ²	F-Statistic	P-Value	Residual Standard Error	Residual Sum of Squares	Residual Mean of Squares
Model 1 Yield	9.072E-01	9.061E-01	7.753E+02	2.200e-16	3.065E-01	4.913E+02	1.000E-01
Model 2 Yield/Area	7.951E-01	7.770E-01	4.403E+01	2.200e-16	4.722E-01	1.085E+03	2.200E-01
Model 3 Value	9.753E-01	9.748E-01	1.885E+03	2.200e-16	1.589E-01	7.111E+01	3.000E-02
Model 4 Value / Area	9.669E-01	9.638E-01	3.095E+02	2.200e-16	1.904E-01	9.528E+01	4.000E-02

3.3.1. F-tests

To determine if predictors significantly related to a Model's response variable, F-tests were conducted. Aside from 3 variables, all F-tests across each model indicated a significant contribution at 95% confidence. The three exceptions were: scope 1 emissions in Model 3 (P=2.221E-01) and Model 4 (P=3.621E-01), and Model 2's interaction between area harvested and water used (P=2.192E-01).

Scope 1 emissions was included in all models to directly compare the response variables as ratios of vineyard size to raw values. Even though not significant within models 3 and 4, when using the Pearson Correlation Coefficients scope 1 emissions was strongly correlated to every Model's response variable; this was especially so for Model 1 and 4 (Yield and average price per tonne as a ratio to area harvested, respectively).

223 3.3.2. *T-tests*

224 T-tests were used to determine if predictors significantly contributed to
225 their models when accounting for other variables; this allowed a more granu-
226 lar examination of interactions and factors within categorical variables, show-
227 ing which specific years and areas contributed significantly and which did not
228 (the appendix contains a comprehensive list of these values).

229 For Models 1 (yield) and 3 (value) year played a pivotal role, with only one
230 year in each model not being significant (2021/2022 and 2016/2017 respec-
231 tively). Both Model 1 and 3 showed a majority of regions were significant
232 with 32 of 54 regions being significant in Model 1, and 42 of 50 regions being
233 significant in Model 3 at 95% confidence.

234 The number of combinations of year and region meant that Models 2 and
235 4 had many tests (424 and 243 respectively). Model 2 found 62.56% of
236 these combinations were indicative of a significant contribution to the model
237 at 95% significance. Model 4 was found to have 88.07% of its year/region
238 combinations indicating a significant contribution. A likely reason for some
239 combinations not being significant was a lack of samples in that particular
240 region/year being present; with region sample sizes ranging from 1 to 1006.

241 With regard to continuous variables: Model 1 and 2 showed all variables to
242 be significant at 95% confidence when accounting for other variables. T-tests
243 for Model 3 showed all continuous variables except scope 1 emissions were
244 significant. Model 4 showed all variables aside from scope 1 emissions and
245 water use to be significant; with scope 1 emissions and water use only being
246 significant when considered as an interaction with area harvested but not
247 when considered on their own.

Table 5: Summary of each Models coefficients for continuous variables

		Area	Water	Scope 1	Area	Area
	Intercept	Harvested	Used	Emissions	Harvested	Harvested
					*	*
					Scope 1	Water
					Emissions	Used
Model 1	-3.318E-02	7.418E-01	8.660E-02	6.731E-02		
Model 2	-6.516E-01	5.774E-01	1.079E-02	8.498E-02	-4.971E-02	-5.346E-02
Model 3	1.808E-02	9.713E-01	-2.310E-02	-6.992E-03		
Model 4	6.702E-01	-7.354E-01	-6.732E-03	-5.645E-03	2.726E-02	7.515E-02

3.3.3. Model Coefficients

The coefficients of each model describe the relationship of a predictor variable to its response when considering all other variables. Due to the transformations of the data, coefficients are individually interpreted in the same manner as the prior regression values were (see Section ??); unlike the regression values, coefficient ranges are not limited between -1 and 1.

We look at the coefficients of categorical and continuous variables separately. This is done as the categorical variables have many coefficients, one for each category, whilst continuous variables have only one. The coefficient for categorical variables is summarised in Figure ??; illustrating the difference in the range as well as affect region and year could have on each model. Comparatively, the continuous variables coefficients are summarised in Table ?. In terms of magnitude, GI region has the highest possible absolute value for each model. An important consideration is that region and year are binary, such that they are only equal to zero or the coefficient (as they

will present as a value of 1 which will be multiplied by the coefficient); this means that, although region may have a strong relationship, it can be overshadowed by an extreme value of one of the continuous variables. The most notable difference between the continuous variables coefficients is the change from positive to negative values. This change occurs between the Models for Yield (Model 1 and 2) and the Models for value (Models 3 and 4); where all but the coefficient for area harvested had the opposite sign (see Table ??). These models also differ in an order of magnitude when looking at resource use, with the coefficients for yield being smaller than those for value.

3.3.4. Model Comparisons: Yield Verse Value

Directly comparing response variables, how crop value changes with yield, also allows an indirect comparison between the response variables and resource use. We do this through using known relationships of response variables to their predictors. These relationships are described by the coefficients. Resource use is described by the predictor variables (through water used and scope 1 emissions), because of this we can observe the response variables somewhat interchangeably with the predictors - although caution should be taken to view them sceptically and alongside the influence of their coefficients. As the predictors are known to have a strong positive correlation with each other, they will tend toward increasing and decreasing together (but not at the same rates). It is also important to consider the interactions of predictor variables when comparing the response variables that are ratios of area. Furthermore, these comparisons require the consideration of the covariates, in this case: area harvested, year and region. Observing Figure ?? shows an almost discrete difference between vineyards

Figure 1: Violin plots of GI Region and Year coefficients for each model.

Figure 2: Scatter plot of vineyard yield against the product of yield and average price per tonne. The axes are in standard deviations with points coloured by climate.

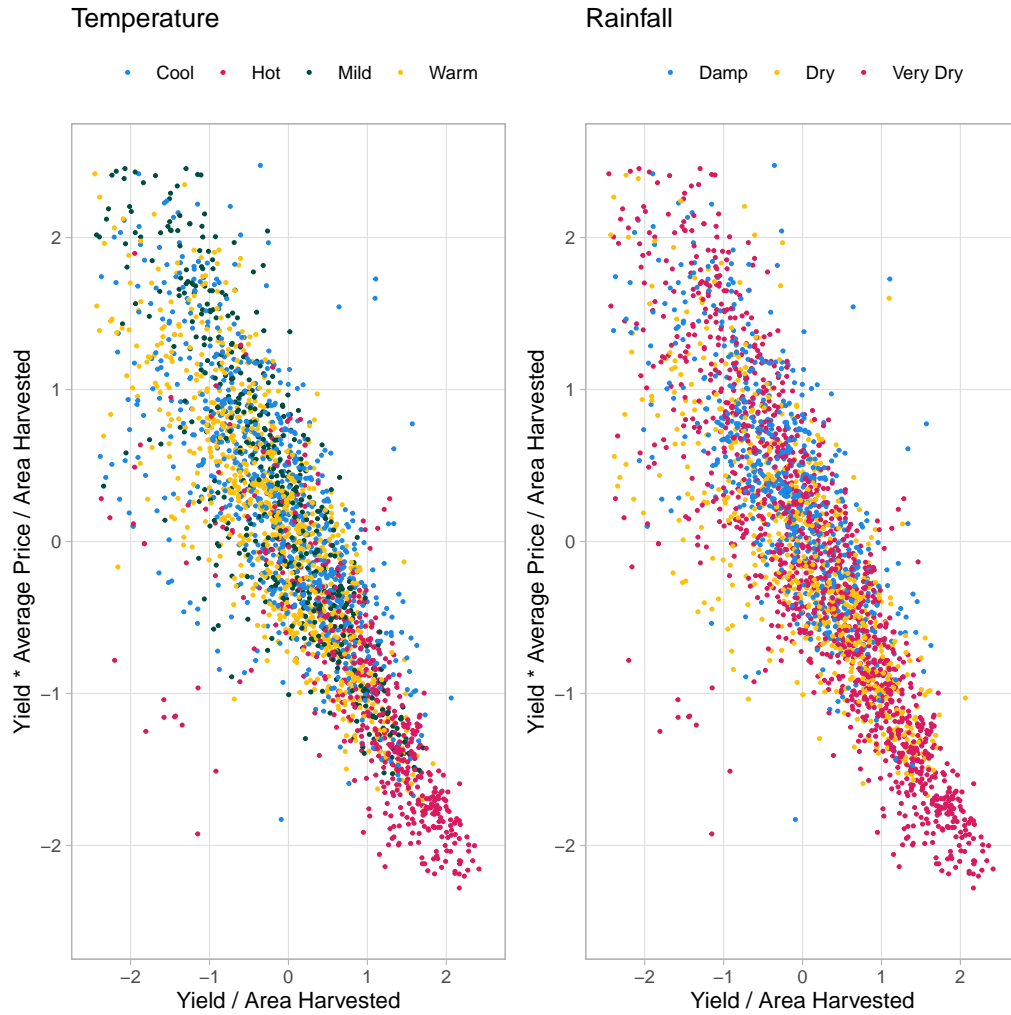

Figure 3: Scatter plot of vineyard yield against the product of yield and average price per tonne as ratios to area harvested. The axes are in standard deviations with points coloured by climate.

Figure 4: Map of regional average yield and value per hectare.

288 in 'Hot' areas than other regions. Comparing Figure ?? to Figure ?? shows
 289 almost opposing trends; a not so obvious difference between the Figures,
 290 is that the difference is mostly a rotation (being a 90 clockwise reflection).
 291 However, with area coming into play, many data points are scaled differ-
 292 ently; specifically the vineyards from 'Hot' regions are then found to be on
 293 the tail end, producing large quantity of lower value grapes. This is more
 294 visible when comparing both graphs to the map of regional averages for re-
 295 sponse variables, see Figure ??. There is a notable change between regional
 296 averages when looking at yield verse value. Through the coefficients we can
 297 deduce that: this difference is also a difference between more resources used
 298 for the raw response variables; and a difference between overall resource use
 299 and the size of the vineyard. Where resource use and area harvested have
 300 a combined relationship through their interaction and separate relationships
 301 as individual variables (see Table ??). A notable occurrence in Figure ??, is
 302 that the 'Very Dry' vineyards which produce lower yields and higher quality
 303 grapes are predominantly found in the Barossa Valley (a wine region known
 304 for its high quality Shiraz). This note is important as it shows climate is not
 305 exclusively the consideration, soil and other geographical phenomenon have
 306 considerable impacts on vineyard outcomes.

307 3.4. Model Validation

308 To validate the performance of these models k-fold cross validation was
 309 used. This was done using 10 folds, $k = 10$, repeated 100 times. The models
 310 performed similarly to their original counter parts (see Table ??).

Table 6: Model validation using k-fold cross validation, for 10 folds repeated 100 times.

	Residual Mean Squared Error	R²	Mean Average Error
Model 1	3.087E-01	9.045E-01	2.165E-01
Model 2	5.104E-01	7.409E-01	3.493E-01
Model 3	1.652E-01	9.723E-01	1.008E-01
Model 4	2.235E-01	9.500E-01	1.279E-01

311 4. Discussion

312 In alternative attempts at models it was found that without the incor-
313 poration of GI Region or year the predictions greatly under performed. The
314 possible reason behind this effect was that different strategies are likely em-
315 ployed between different regions, where some regions target the mass pro-
316 duction of cheaper grapes over quality.

317 Reviewing the data to uncover reasons for this included the use of binary
318 variables such as the utilisation of renewable energy, contractors, and the
319 occurrence of disease, fire and frost; however none of these variables were able
320 to explain why some vineyards produced less, or why other vineyards sold at
321 higher prices than predicted. A wide variety of these influences were likely
322 already explained within the use of year and GI Region, or the interaction
323 of both variables. The change between some regions was dramatic, with
324 particularly warmer and drier regions producing much higher volumes of
325 grapes at lower prices (See Figures 5 and 6). The use of other variables and

326 methods, specifically splines, were able to create a more normally distributed
327 set of residuals but at a drastically reduced accuracy when comparing R2 and
328 RSE. The introduction of known average prices per tonne also helped increase
329 R2 values a small amount; it is important to not that it is common practice
330 for wineries to purchase grapes at a regional average rate, likely resulting in
331 much less variance within a region.

332 different strategies are likely employed between different regions, where
333 some regions target the mass production of cheaper grapes over quality. This
334 is most notable when grouping regions by climate, especially when considering
335 GI Regions in the 'Hot Very Dry' climate (see Figure 7). The effect of
336 climate in the models was not more significant than the more granular use
337 of GI regions. The interaction between year and GI Region likely accounted
338 for localised events such as bushfires, which would be impactful, but only at
339 a local level in both time and space.

340 *4.1. Limitations*

341 Limitations included overestimating yield for models 1 and 2, (see Fig-
342 ures 1 and 2) and underestimating crop value in models 3 and 4 (see Figures
343 3 and 4). This study investigated the general relationships between input
344 resources of a vineyard, including fuel and water, and the outputs including
345 yield and value. Some regions appeared to produce many low quality grapes
346 at scale compared to attempting to produce fewer higher quality grapes. This
347 behaviour can be observed when reviewing Wine Australia's annual reports,
348 where it is apparent that warm inland regions such as the Riverland are
349 known to only produce large amounts of lower graded grapes ???. Compar-
350 atively, regions such as Tasmania only produce A grade grapes but in much

351 smaller quantities than the Riverland. Knowing that the difference in pricing
352 per tonne can exceed a magnitude of 10 between grades E and A, the op-
353 erations in regions that target different grades would have varied priorities.
354 However, some regions such as the Yarra Valley produce a Variety of different
355 grades of grapes, from C to A, highlighting that vineyard priorities, although
356 may be somewhat present within regional classifications, are not necessarily
357 aligned within a given region.

358 The opportunity to target different grades of grapes may not always be
359 available, with some regions being more renowned than others, and likely to
360 be sought after regardless (?). The Barossa is an example of this, known
361 for its quality could also lend itself to a bias in purchasers not considering
362 other regions that may be capable of similar quality. This effect could stifle
363 the potential for market opportunities within these lesser known regions.
364 A further possibility is that there may be regional upper limits with the
365 relationship between resource input and the value gained becoming no longer
366 proportional due to diminishing returns. Climate was considered to be a large
367 determinant of the ability to grow a larger quantity of grapes, as well as a
368 determinant in grape quality (?); however there were vineyards in similar
369 regions that were able to produce exceptionally better results than others
370 (See Figure 7).

371 The issue of model 1 and 2 over predicting yield, may have been due to
372 preventative measures brought on by regional pressures such as fire, frost and
373 disease. Where, more resources were required to prevent these issues from
374 spreading within a region, thus disproportionately affecting some vineyards
375 compared to others locally. This type of maintenance is not well captured

376 especially when considering that some regions, those in warmer areas are
377 not as prone to disease as cooler climates and could potentially have lower
378 operating costs per hectare. This could create a discrepancy in vineyards that
379 utilise preventative measures in wetter regions, as opposed to those who do
380 not, and thus expend less fuel and energy but risk disease. When reviewing
381 the differences between regions it is important to consider that vineyards
382 in Hot Very Dry areas can be hundreds of times the size of those in other
383 regions. It is interesting that while area, although significantly correlated to
384 the ratio of yield to area, was still lower than water and about the same as
385 emissions. This points to economies of scale playing a role but still being
386 only one consideration alongside the potential resources that can be used.
387 The negative trend between size and average sales price could also be a side
388 effect of mass supply verse demand, especially when looking at the level of
389 difference in production of some vineyards (see Table 4). The relationships
390 between yield, value and area are not simply about efficiently producing the
391 most grapes; sales price and by association grape quality, are integral to the
392 profitability, and this is strongly linked to resource-use and thus the longevity
393 and sustainability of a vineyard.

394 Literature shows that there are many on-the-ground decisions that influ-
395 ence both quality and yield. Where these decisions are governed by complex
396 physical and social forces such as international market demands, disease pres-
397 sures and natural disasters (???????). Many of these occurrences being high-
398 lighted throughout the past decades vintage reports (?????????). It is also
399 important to consider that these reports show that the warm inland regions
400 have seen a decline in profit during this period, as they were often compared

401 to other regions that focused more on quality than quantity. This is an im-
402 portant consideration, as the size of some of these vineyards when considering
403 their ratio of value to area would only require a marginal increase to out com-
404 pete other regions. There are also differences when comparing winegrowers
405 to other agricultural industries as they are vertically integrated within the
406 wine industry, tying them to secondary and tertiary industries, such as wine
407 production, packaging, transport and sales. This results in unique issues and
408 considerations for each vineyard, where these on-the-ground decisions may
409 be influenced by other wine industry’s choices, such as the use of sustain-
410 able practices in vineyards as a requirement for sale in overseas markets;
411 notably these interactions are further complicated by some winegrowers be-
412 ing totally integrated into wine companies, while others are not (Knight et
413 al., 2019). Incorporating such decisions into the model could help describe
414 the contributing factors to regional differences beyond resource consumption
415 and regional differences.

416 Having more data for each region would also be an improvement, allowing
417 greater comparison between regions. More variables may also help to discern
418 vineyards that can produce larger volumes of grapes at higher prices. The use
419 of semi transparent tools such as random forests and decision trees alongside
420 more variables and data may help to uncover the reasons for values that
421 were under or over estimated. These differences could be caused by the use
422 of alternative sustainable practices in the field. While there is evidence to
423 suggest that environmentally sustainable practices can reduce costs, increase
424 efficiency, whilst improving the quality of grapes, more research is needed to
425 link these benefits across different regions and climates (???).

426 The relationship between scope one emissions and the response variables
427 that included average sales price

428 It is possible that the relationships between scope one emissions and the
429 response variables were closely tied to a vineyards area. This possibility could
430 be explained through the emissions

431 Noting that irrigation systems use fuel and that the application of water
432 was a significant variable in each model scope one emissions' lack of signifi-
433 cance and contribution given its F-statistics (See Tables 7 and 8), indicated
434 that it is possible other vineyard activities requiring fuel are not as deter-
435 mining factors for a vineyards grape quality.
